BNB CHAIN · BEP-20

Omniverse Compute (OMC)

Decentralized GPU computing network — inference, fine-tuning and batch rendering on hardware strangers own.

Whitepaper Deck v3.1 · omc.network · October 2026

Informational only — not an offer to sell or buy any token.

EXECUTIVE SUMMARY

Three ideas behind OMC

01

Honest scope

Inference, single-node fine-tuning, batch rendering and other embarrassingly parallel jobs — not frontier-scale cluster training.

02

Verification you can price

A per-job policy: spot-check re-execution, optional full redundancy, TEE where available, staking and slashing. The buyer chooses the cost of certainty.

03

Demand tied to usage

Fees are paid per job: **50% burned, 30% to stakers, 20% to the treasury**. Emission is capped by trailing fee revenue, so supply growth is a function of demand.

WHAT AN INVESTOR SHOULD BE ABLE TO CHECK	WHERE
Protocol fee and its split	8% at settlement · 50 / 30 / 20 — `contracts/params.json → fees`
Emission ceiling and the gate that binds it	`min(ceiling, k × 30-day fee revenue)` — `params.json → emission.revenueGate`
Circulating supply at TGE	65,500,000 OMC · 6.55% — no team unlock at TGE
Cost to take part in the airdrop	0.01 BNB per entry at claim, not refunded (0.05 BNB for a five-entry claim) — published, not discovered

PROBLEM

Compute is scarce, expensive and centralized

Demand

AI developers face high hourly prices, regional quota limits and vendor lock-in. Studios face sharp render peaks they cannot size hardware for.

Supply

Consumer GPUs, small data-center idle capacity and post-PoW hardware sit underused — most of it for most of the day.

The gap

There is no widely trusted way for strangers to rent GPU time with enforceable guarantees about correctness, privacy and payment.

The answer

OMC matches a job to a staked node, holds the payment in escrow, verifies the result by policy, and pays only on settlement. The stake is what the buyer gets back if the result is wrong.

> **Why it is not just a marketplace.** A marketplace without staking is a forum with a wallet: the default is a dispute nobody can price. Every node posts a bond in USD terms, and slashing pays the wrongful party, so a bad result has a cost that is known before the job is submitted.

TARGET USERS

Who runs what on OMC

AI startups & developers

Inference, LoRA/QLoRA fine-tuning, batch embeddings — lower cost, no quota waiting.

Web3 & DeAI projects

Agent inference and batch workloads with crypto-native payment and no account.

Rendering & 3D studios

Blender and UE offline rendering with per-job pricing and burst capacity.

GPU owners & small DCs

Monetize idle hardware with earnings that depend on work actually delivered.

> The first three are the demand side and the last is supply. **A network that only has the fourth is a token with a dashboard**, which is why the fee split pays stakers only from settled volume.

ARCHITECTURE

Scheduling in two stages

Stage 1 — hard filters

VRAM, driver and CUDA/ROCm version, region, confidential-computing requirement, minimum stake and reputation. A node that cannot run the job is not a candidate.

Stage 2 — weighted scoring

Each metric becomes a percentile rank among eligible nodes. A weighted matching problem maximizes total score, and the final pick is drawn at random from the top-k.

DESIGN CHOICE	WHY
Random pick from top-k, not the single best	A deterministic winner is a target for capture and a fixed job history for its owner.
Percentile ranks, not raw scores	One node with an unusual GPU cannot dominate every category.
Reputation is earned from settled jobs	It cannot be bought, and it is slashed with the stake.

VERIFICATION AND TRUST

No single technique verifies every workload

MECHANISM	HOW IT WORKS	COST TO REQUESTER
Spot-check re-execution	A random share of jobs is silently re-run on an independent node; a mismatch triggers slashing	+5–10%
Full redundancy	The job runs on 2–3 independent nodes and outputs are compared	2× – 3×
Confidential computing (TEE)	Hardware-protected execution with remote attestation, for inputs that cannot be re-run	Tier-dependent
Stake and slashing	The floor under all of the above: a wrong answer costs the node its bond	Included

> **What this does not claim.** Deterministic proof of arbitrary GPU work is an open problem, and this deck does not say otherwise. The product is a priced probability of correctness, chosen per job — not a claim that every result is provably right.

SECURITY AND PRIVACY

Explicit about what cannot be guaranteed

Isolation

Hardened sandboxes — gVisor by default, Kata microVM tiers for sensitive workloads. No host access, no outbound network by default.

Encryption

Inputs, outputs and images encrypted in transit and at rest. Keys are released only after assignment.

Three protection levels

Standard, **Protected** (ephemeral, wiped after the job) and **Confidential** (TEE-only nodes).

> On a node the operator physically controls, isolation is a mitigation, not a proof. That is why the protection level is the buyer's choice and is priced: a workload that cannot tolerate the residual risk should select Confidential and pay for it.

ECONOMICS

Fee flows tied to real usage

FLOW	SPLIT OF THE 8% FEE
Burn at settlement	50% → 4.0% of GMV destroyed
Stakers, pro rata to stake	30% → 2.4% of GMV
Treasury	20% → 1.6% of GMV

> Payments in OMC carry a **10% fee discount** (8% → 7.2%). Unstaking has a **14-day cooldown**: a bond that can leave in the same block as a bad job is not a bond.

EMISSION CONTROL	RULE
Daily emission	`min(annualCeiling ÷ 365, k × trailing30dFeeRevenue ÷ 30)`
k, year 1 → 6	3 · 2 · 1.5 · 1 · 0.75 · 0.5
Burn ÷ emission	17% → 25% → 33% → 50% → 67% → **100%**

> No revenue means no emission. The schedule is a ceiling that only binds when the network is earning, and the ratio of burn to emission is **independent of GMV and price** inside the gate.

TOKEN DISTRIBUTION

1,000,000,000 OMC fixed supply (BEP-20)

CATEGORY	SHARE	AMOUNT	VESTING
Compute mining & node rewards	50%	500,000,000	0% at TGE — 400M scheduled, 100M DAO reserve locked until 2037
Ecosystem & grants	15%	150,000,000	5% at TGE, 6m lock, then 36m monthly
Institutional investors	10%	100,000,000	5% at TGE, 6m cliff, then 24m monthly
Team & core contributors	10%	100,000,000	0% at TGE, 12m cliff, then 24m monthly
Private investors	8%	80,000,000	10% at TGE, 3m cliff, then 18m monthly
Treasury & liquidity	5%	50,000,000	50% at TGE for DEX/CEX liquidity
Community airdrop	2%	20,000,000	100% at claim · 1,000,000 entries × 20 OMC · 0.01 BNB per entry
Circulating at TGE	**6.55%**	**65,500,000**	**No team tokens. No node rewards.**

> The TGE float is 25M treasury liquidity + the whole 20M airdrop (paid out in full at claim) + 8M private + 7.5M ecosystem + 5M institutional. The airdrop counts at 100% because it is paid out in full at claim: the pool is either liquid on the day the window opens or the page is advertising a number the claimer never receives. That is 2% of supply, and every wallet selling into it paid 0.01 BNB per entry for the position.

EMISSION

A ceiling, not an entitlement

YEAR	1	2	3	4	5	6–10
Annual ceiling (OMC)	10M	20M	30M	40M	50M	50M
Gate multiplier k	3	2	1.5	1	0.75	0.5
Burn ÷ emission at the gate	17%	25%	33%	50%	67%	100%

400M
scheduled over 10 years, linear by day

100M
DAO reserve, unmintable before 2037-01-01

100%
burn ÷ emission from year 6 — supply stops growing

> Scheduling the whole 500M pool would have forced late-year ceilings up to 60M purely to make the arithmetic balance. The reserve is a governance decision in 2037, not a line in a spreadsheet.

STAKING AND SLASHING

Five hardware tiers, priced in USD

TIER	HARDWARE	MIN. STAKE
1	Consumer GPU, up to 24 GB (3090 / 4090)	$250
2	Workstation GPU (A6000, L40S)	$1,000
3	Data-center GPU, 80 GB (A100 / H100)	$5,000
4	Multi-GPU node (2–8 accelerators)	$15,000
5	Cluster-scale deployment	$50,000

> The bond is quoted in USD and converted at stake time, so a falling token price does not quietly reduce the collateral behind a job.

OFFENCE	PENALTY
Job timeout	2%
Offline during a job	5%
Incorrect output	30%
Proven fraud	100%

> Slashing is split **50% to the wronged requester, 30% to the treasury, 20% burned**. Unstaking has a 14-day cooldown.

GOVERNANCE AND ROADMAP

From team-led to community-led

Launch

4-of-7 multisig of core contributors with a 3-day timelock. Signers not disclosed at this stage.

Transition

Holder votes on parameters and treasury spending: 100,000 OMC threshold, 10% quorum, 7-day voting, 2-day delay.

Full DAO

2027 or later. The multisig is removed or limited to emergency actions.

PHASE	TARGET	SCOPE
Phase 1	Q4 2026 · in progress	Testnet: BEP-20 tOMC, staking, compute market, node client, airdrop campaign
Phase 2	1 January 2027	Mainnet, TGE, staking and the airdrop claim window open on the same date
Phase 3	2027 Q4 and later	TEE production, ZK research, full DAO; the L2 path stays a plan until it has a deployment

LEARN MORE

Where to verify everything

RESOURCE	WHAT IT IS
omc.network	Whitepaper v3.0, tokenomics, testnet, airdrop campaign
forum.omc.network	DCF — GPU market research, a 12-network comparison tracker, the run-a-node guide
top.omc.network	AITop — tool comparisons and rankings for buyers of compute
github.com/CBTdao/omc-network	Node client, contracts, parameters, and the models that produce every number in this deck
support@omc.network · security@omc.network	Questions, and vulnerabilities

> Every figure here is generated by `models/economics.mjs` and `models/claim.mjs` from `contracts/params.json`, and checked by the tests in the repository. If a number in this deck disagrees with the repository, the repository is right — that is a build error, not a version difference.
